We used geometric algebra to compute the paths of skew rays in a cylindrical, step-index multimode optical fiber. To do this, we used the vector addition form for the law of propagation, the exponential of an imaginary vector form for the law of refraction, and the juxtaposed vector product form for the law of reflection. In particular, the exponential forms of the vector rotations enables us to take advantage of the addition or subtraction of exponential arguments of two rotated vectors in the derivation of the ray tracing invariants in cylindrical and spherical coordinates. We showed that the light rays inside the optical fiber trace a polygonal helical path characterized by three invariants that relate successive reflections inside the fiber: the ray path distance, the difference in axial distances, and the difference in the azimuthal angles. We also rederived the known generalized formula for the numerical aperture for skew rays, which simplifies to the standard form for meridional rays. © 2015 Optical Society of America

1. INTRODUCTION

Optical fibers are waveguides used for optical communication as first illustrated by Tyndall in 1870 [1]. Single-mode fibers have radii of about 8 μm , while multimode fibers have about 60 μm [2]. The description of light propagation in single-mode fibers requires wave optics, while in multimode fibers, the ray approximation is sufficient [3]. In this paper, we shall only talk of multimode fibers using ray or geometric optics, i.e., no diffraction, interference, or polarization.

Optical fibers can be classified depending on the functional dependence of the refractive index on the fiber radius: step-index or graded-index. Step-index can be multistep [4], while graded-index fibers can have refractive index functions that are parabolic. Here, we shall focus only on step-index fibers, where the refractive index of the core is constant and light rays are guided through total internal reflection.

If the rays lie only on a single plane, the rays are said to be meridional; if the rays trace a discrete helix, the rays are skew. Most textbooks describe only the meridional rays and mention skew rays only in passing. The reason for this is that the mathematics used to describe skew rays is difficult [5–7].

The study of geometric optics ray tracing for skew rays is still an important problem for two reasons. The first is pedagogical: skew ray tracing for laser light in large fibers, e.g., HeNe laser in 1 cm diameter glass fiber, can be used to verify the helical properties of skew rays in a student laboratory. The second is

practical: skew ray tracing equations can serve as the starting point for the analysis of electric fields at the fiber walls [8] and can provide the basis of ray tracing algorithms for optical fibers [9], which may even include the Goos–Hänchen effect for reflection [10].

To construct a ray tracing algorithm, we need to describe rays mathematically. We can do this in three ways.

The first way is by labeling points, lines, and angles, then using geometry and trigonometry to determine the scalar invariants, e.g., the axial path length between reflections, axial angle of incident and reflected rays, and the numerical aperture (NA). But the system for naming these geometrical quantities varies from author to author, making it difficult to compare results [3,11–14]. To solve the problem of the angle naming conventions, we define the directions of the vectors in terms of the polar angles θ and the azimuthal angle ϕ in spherical coordinates, distinguished only by their subscripts, e.g., θ_σ and ϕ_σ for the incident ray σ and ϕ_η for the normal vector η .

The second way is to use vectors for ray tracing. In general, we need five vectors: the initial position of the ray \mathbf{r} , the final position of the ray \mathbf{r}' , the propagation vector σ , the reflected vector σ' , and the vector normal to the surface η' . The task of ray tracing then is to relate these variables using a set of equations, such as those given in Klein and Furtak [15], though in a slightly different form involving the concavity function $c_{\sigma\eta k} = \pm 1$:

$$\mathbf{r}_{k+1} = \mathbf{r}_k + s_{k+1} \boldsymbol{\sigma}_{k+1}, \quad (1a)$$

$$\boldsymbol{\sigma}'_k = \boldsymbol{\sigma}_k - 2c_{\sigma\eta k} \boldsymbol{\eta}_k \cos \beta_k, \quad (1b)$$

$$n_{k+1} \boldsymbol{\sigma}_{k+1} = n_k \boldsymbol{\sigma}_k + c_{\sigma\eta k} (n_{k+1} \cos \beta_{k+1} - n_k \cos \beta_k) \boldsymbol{\eta}_k, \quad (1c)$$

which corresponds to propagation, reflection, and refraction. But these ray tracing equations are difficult to apply if we wish to compute for analytic solutions, such as reflected ray and final position after a certain number of reflections within the fiber. That is why ray tracing algorithms do not use analytical solutions but rather iterative computations using the equations described [9,10].

The third way is to use vectors in ray tracing but within the framework of the Eikonal method [16,17]. Here, the position \mathbf{R} of the ray satisfies a vector differential equation:

$$\frac{d}{ds} \left(n \frac{d\mathbf{R}}{ds} \right) = \nabla n, \quad (2)$$

where s is the propagation distance and n is the refractive index. This method lends itself readily to the analysis of invariants in step-index fibers, as shown by Zubia *et al.* [4]. This method may also be applied to graded-index fibers using computational methods [9,18,19]. This differential equation approach may be powerful and lends itself well to computational methods, but it does not exploit the simple vector geometry of rays for step-index fibers.

In this paper, we shall not use the Eikonal method nor the reflection and refraction equations in Eqs. (1b) and (1c). Instead, we shall construct the ray tracing equations using the exponential rotational operators and direct vector products in geometric algebra:

$$\mathbf{ab} = \mathbf{a} \cdot \mathbf{b} + i\mathbf{a} \times \mathbf{b}, \quad (3a)$$

$$e^{i\mathbf{n}\theta} = \cos \theta + i\mathbf{n} \sin \theta, \quad (3b)$$

which are the Pauli identity [20,21] and Euler's theorem, respectively. For example, the law of reflection and refraction can be expressed as

$$\boldsymbol{\sigma}_{k+1} = -\boldsymbol{\eta}_k \boldsymbol{\sigma}_k \boldsymbol{\eta}_k, \quad (4a)$$

$$\boldsymbol{\sigma}_{k+1} = \boldsymbol{\sigma}_k e^{ic_{\sigma\eta k} \boldsymbol{\eta}_k (\beta_k - \beta_{k+1})}. \quad (4b)$$

The direct vector product form of the law of reflection [21–23] in Eq. (4a) and the exponential rotation form of the law of refraction [24] in Eq. (4b) were already known before. These laws and their variants were used in geometric optics for the derivation of ray tracing equations for spherical lenses and mirrors for different ray cases: finite skew, paraxial skew, finite meridional, and paraxial meridional [25,26]. Equations (4a) and (4b) were also used before in the derivation of skew ray tracing equations in optical fibers [14]; however, the treatment in this three-page extended conference abstract is limited and does not include the discussion of the NA. We shall correct these in this paper.

We shall divide the paper into five sections. Section 1 is an introduction. In Section 2, we shall describe the basics of geometric algebra and how it can be used for vector rotations

in different coordinate systems. We shall use this algebra to describe the laws of propagation, reflection, and refraction in geometric optics. In Section 3, we shall derive the distances and angles of propagation of the light rays inside the fiber and compute the fiber's NA. In Section 4, we shall summarize the ray tracing invariants. Section 5 is conclusions.

2. GEOMETRIC ALGEBRA FOR GEOMETRIC OPTICS

A. Geometric Algebra

1. Vectors and Imaginary Numbers

Geometric algebra $Cl_{3,0}$, known as Pauli algebra [20], is generated by three spatial unit vectors \mathbf{e}_1 , \mathbf{e}_2 , and \mathbf{e}_3 , which satisfy the orthonormality axioms [27]

$$\mathbf{e}_j^2 = 1, \quad (5a)$$

$$\mathbf{e}_j \mathbf{e}_k = -\mathbf{e}_k \mathbf{e}_j. \quad (5b)$$

That is, the square of a vector simply is unity and the juxtaposition multiplication product of two distinct unit vectors anticommute with each other.

We can generalize these multiplication rules for two arbitrary vectors \mathbf{a} and \mathbf{b} in 3D using the Pauli identity [20,21]

$$\mathbf{ab} = \mathbf{a} \cdot \mathbf{b} + i(\mathbf{a} \times \mathbf{b}), \quad (6)$$

where $i = \mathbf{e}_1 \mathbf{e}_2 \mathbf{e}_3$. It can be shown that i is an imaginary number that commutes with both scalars and vectors.

If we express \mathbf{a} as the sum of its perpendicular and parallel vector components with respect to \mathbf{b} , then

$$\mathbf{a} = \mathbf{a}_\perp + \mathbf{a}_\parallel. \quad (7)$$

Using the Pauli identity in Eq. (6), we can show that

$$\mathbf{a}_\parallel \mathbf{b} = \mathbf{a}_\parallel \cdot \mathbf{b} = \mathbf{ba}_\parallel, \quad (8a)$$

$$\mathbf{a}_\perp \mathbf{b} = \mathbf{a}_\perp \times \mathbf{b} = -\mathbf{ba}_\perp. \quad (8b)$$

Equation (8) is the 3D generalization of the orthonormality axiom in Eq. (5).

2. Rotations

Let θ be a scalar and \mathbf{n} be a unit vector. Since $(i\mathbf{n})^2 = -1$, then we may use Euler's theorem:

$$e^{i\mathbf{n}\theta} = \cos \theta + i\mathbf{n} \sin \theta. \quad (9)$$

Now, suppose \mathbf{a}_\perp and \mathbf{a}_\parallel are the components of \mathbf{a} perpendicular and parallel to \mathbf{n} . Multiplying these from the left of Eq. (9), and using the commutation and anticommutation rules in Eq. (8), we obtain

$$\mathbf{a}_\parallel e^{i\mathbf{n}\theta} = e^{i\mathbf{n}\theta} \mathbf{a}_\parallel, \quad (10a)$$

$$\mathbf{a}_\perp e^{i\mathbf{n}\theta} = e^{-i\mathbf{n}\theta} \mathbf{a}_\perp. \quad (10b)$$

Notice that a change in sign of the exponential's argument occurs only when the exponential is multiplied to \mathbf{a}_\perp .

If we expand the left side of Eq. (10b), we get

$$\mathbf{a}_\perp e^{i\mathbf{n}\theta} = \mathbf{a}_\perp (\cos \theta + i\mathbf{n} \sin \theta). \quad (11)$$

Distributing the terms, and using the Pauli identity in Eq. (6), we obtain

$$\mathbf{a}_\perp e^{i\theta} = \mathbf{a}_\perp \cos \theta - (\mathbf{a}_\perp \times \mathbf{n}) \sin \theta, \quad (12)$$

since $\mathbf{a}_\perp \cdot \mathbf{n} = 0$. Geometrically, $\mathbf{a}_\perp e^{i\theta}$ is the vector \mathbf{a}_\perp rotated counterclockwise about a unit vector \mathbf{n} .

3. Coordinate Systems

We claim that the unit radial vector \mathbf{e}_r in spherical coordinates is given by [23]

$$\mathbf{e}_r = e^{-ie_3\phi/2} \mathbf{e}_3 e^{ie_2\theta} e^{ie_3\phi/2}. \quad (13)$$

To show this, we note that from Eq. (12),

$$\mathbf{e}_3 e^{ie_2\theta} = \mathbf{e}_3 \cos \theta + \mathbf{e}_1 \sin \theta, \quad (14)$$

so that Eq. (13) may be written as

$$\mathbf{e}_r = e^{-ie_3\phi/2} (\mathbf{e}_3 \cos \theta + \mathbf{e}_1 \sin \theta) e^{ie_3\phi/2}. \quad (15)$$

Distributing the terms and using the relations in Eq. (10), we get

$$\mathbf{e}_r = \mathbf{e}_3 \cos \theta + \mathbf{e}_1 \sin \theta e^{ie_3\phi}. \quad (16)$$

Hence,

$$\mathbf{e}_r = \mathbf{e}_1 \sin \theta \cos \phi + \mathbf{e}_2 \sin \phi \sin \theta + \mathbf{e}_3 \cos \theta. \quad (17)$$

Equation (17) is the representation of the unit spherical radial vector \mathbf{e}_r in rectangular coordinates, as shown in Fig. 1.

B. Geometric Optics

1. Law of Propagation

If a light ray moves from its initial position \mathbf{r}_k at the k th interface by a distance s_{k+1} in the direction of the unit vector σ_{k+1} , then the ray's final position \mathbf{r}_{k+1} at the $(k+1)$ th interface is [24]

$$\mathbf{r}_{k+1} = \mathbf{r}_k + s_{k+1} \sigma_{k+1} \quad (18)$$

(see Fig. 2). Note that we can express \mathbf{r}_k , \mathbf{r}_{k+1} , σ_k as the sum of \mathbf{e}_3 and $\mathbf{e}_1 e^{ie_3\phi}$ as given in Eq. (16):

$$\mathbf{r}_k = z_k \mathbf{e}_3 + r_k \sin \theta_k \mathbf{e}_1 e^{ie_3\phi_k}, \quad (19a)$$

$$\mathbf{r}_{k+1} = z_{k+1} \mathbf{e}_3 + r_{k+1} \sin \theta_{k+1} \mathbf{e}_1 e^{ie_3\phi_{k+1}}, \quad (19b)$$

$$\sigma_{k+1} = \cos \theta_{\sigma(k+1)} \mathbf{e}_3 + \sin \theta_{\sigma(k+1)} \mathbf{e}_1 e^{ie_3\phi_{\sigma(k+1)}}, \quad (19c)$$

then Eq. (18) can be separated into simultaneous equations for each component:

$$\begin{aligned} r_{k+1} \sin \theta_{k+1} \cos \phi_{k+1} &= r_k \sin \theta_k \cos \phi_k \\ &+ s_{k+1} \sin \theta_{\sigma(k+1)} \cos \phi_{\sigma(k+1)}, \end{aligned} \quad (20a)$$

$$\begin{aligned} r_{k+1} \sin \theta_{k+1} \sin \phi_{k+1} &= r_k \sin \theta_k \sin \phi_k \\ &+ s_{k+1} \sin \theta_{\sigma(k+1)} \sin \phi_{\sigma(k+1)}, \end{aligned} \quad (20b)$$

$$r_{k+1} \cos \theta_{k+1} = r_k \cos \theta_k + s_{k+1} \cos \theta_{\sigma(k+1)}. \quad (20c)$$

2. Law of Reflection

Let σ_k be the direction of the ray as it hits the k th interface with a unit normal vector η_k . The new direction σ_{k+1} after it hits the interface is [23]

$$\sigma_{k+1} = -e^{-i\eta_k\pi/2} \sigma_k e^{i\eta_k\pi/2}. \quad (21)$$

That is, the reflected ray σ_{k+1} is the negative of the incident ray σ_k rotated counterclockwise about η_k by an angle π . Expanding the exponentials using the Euler identity Eq. (9), then Eq. (21) reduces to

$$\sigma_{k+1} = -\eta_k \sigma_k \eta_k, \quad (22)$$

which is a known form for the reflection law in geometric algebra [23].

If we rewrite the product $\eta_k \sigma_k$ in Eq. (22) using the Pauli identity in Eq. (6) and distribute the rightmost η_k , we get

$$\sigma_{k+1} = -(\eta_k \cdot \sigma_k) \eta_k + i(\eta_k \times \sigma_k) \eta_k. \quad (23)$$

Applying the Pauli identity again for the second term results to

$$\sigma_{k+1} = -\eta_k (\eta_k \cdot \sigma_k) + (\eta_k \times \sigma_k) \times \eta_k, \quad (24)$$

since $i(\eta_k \times \sigma_k) \cdot \eta_k = 0$. Finally, expanding the triple cross product on right-hand side, Eq. (24) becomes

$$\sigma_{k+1} = -2\eta_k (\eta_k \cdot \sigma_k) + \sigma_k. \quad (25)$$

Let us define β_k as the angle of incidence, so that

$$\eta_k \cdot \sigma_k = c_{\sigma\eta k} \cos \beta_k, \quad (26)$$

where $c_{\sigma\eta k}$ is the concavity function,

$$c_{\sigma\eta k} = \frac{\sigma_k \cdot \eta_k}{|\sigma_k \cdot \eta_k|}, \quad (27)$$

whose values are ± 1 . Thus, Eq. (25) reduces to

$$\sigma_{k+1} = -2\eta_k \cos \beta_k + \sigma_k, \quad (28)$$

which is the same expression for the law of reflection in Klein and Furtak [15,24].

3. Law of Refraction

The law of refraction is given by

$$n \sin \beta = n' \sin \beta', \quad (29)$$

where n and n' are the indices of refraction at both sides of the interface, while β and β' are the angles of incidence and refraction.

The refraction law in Eq. (29) may also be reformulated in geometric algebra as follows [24]:

$$\sigma_{k+1} = \sigma_k e^{ic_{\sigma\eta} \mathbf{e}_{\sigma\eta} (\beta - \beta')}, \quad (30)$$

where σ_k is the incident vector, σ_{k+1} is the refracted vector, $c_{\sigma\eta k}$ is the concavity function in Eq. (27), and $\mathbf{e}_{\sigma\eta k}$ is the axis of rotation,

$$\mathbf{e}_{\sigma\eta k} = \frac{\sigma_k \times \eta_k}{|\sigma_k \times \eta_k|}, \quad (31)$$

where η_k is the unit vector normal to the surface. Geometrically, Eq. (30) says that the refracted ray is the incident ray rotated either clockwise (if the concavity function is negative/interface is convex) or counterclockwise (if the concavity function is positive/interface is concave) about $\mathbf{e}_{\sigma\eta k}$ by the difference of the incident angle and the refracted angle, $\beta - \beta'$. We will use primed variables for the refracted values. Also, we shall mostly deal with concave surfaces inside the fiber, so that we can immediately set $c_{\sigma\eta k} = +1$.

3. SKEW RAYS IN OPTICAL FIBERS

A. Refraction at Point P_i

Let σ_i be the direction of the initial ray as it strikes the flat end of the fiber:

$$\sigma_i = \sin \theta_{\sigma_i} \mathbf{e}_1 e^{i\mathbf{e}_3 \phi_{\sigma_i}} + \cos \theta_{\sigma_i} \mathbf{e}_3, \quad (32)$$

which is similar in form to Eq. (19c). If the ray σ_i strikes the fiber at the position \mathbf{r}_i , then the outward normal vector at the surface is

$$\eta_i = -\mathbf{e}_3. \quad (33)$$

Multiplying Eq. (32) and Eq. (33), and using the exponential identities in Eq. (8), we get

$$\sigma_i \eta_i = \sin \theta_{\sigma_i} \mathbf{e}_2 e^{i\mathbf{e}_3 \phi_{\sigma_i}} - \cos \theta_{\sigma_i}. \quad (34)$$

Expanding the left-hand side of Eq. (34) using the Pauli identity in Eq. (6), and separating the scalar and vector parts, we obtain

$$\sigma_i \cdot \eta_i = -\cos \theta_{\sigma_i}, \quad (35a)$$

$$\sigma_i \times \eta_i = \sin \theta_{\sigma_i} \mathbf{e}_2 e^{i\mathbf{e}_3 \phi_{\sigma_i}}. \quad (35b)$$

Substituting these into the definition of the concavity function and the rotation axis in Eqs. (27) and (31), we arrive at

$$c_{\sigma\eta i} = -\frac{\cos \theta_{\sigma_i}}{|\cos \theta_{\sigma_i}|} = -1, \quad (36a)$$

$$\mathbf{e}_{\sigma\eta i} = \mathbf{e}_2 e^{i\mathbf{e}_3 \phi_{\sigma_i}}, \quad (36b)$$

since $\theta_{\sigma_i} > 0$.

We can find the angle β_i between the unit vectors σ_i and η_i using their dot product:

$$\sigma_i \cdot \eta_i = \cos \beta_i = \cos \theta_{\sigma_i}, \quad (37)$$

so that

$$\beta_i = \theta_{\sigma_i}. \quad (38)$$

Using Snell's law, the refracted angle β'_i is given by

$$\beta'_i = \sin^{-1} \left(\frac{n}{n'} \sin \beta_i \right), \quad (39)$$

where we set $n = 1$ for air (see Fig. 3).

The law of refraction as given by Eq. (30) for $k = 0$ is

$$\sigma_0 = \sigma_i e^{i(\beta_i - \beta'_i) \mathbf{e}_{\sigma\eta i}}, \quad (40)$$

where $c_{\sigma\eta 1} = 1$. We can express σ_i as a rotation of \mathbf{e}_3 about the axis $\mathbf{e}_{\sigma\eta 1}$ by a clockwise angle β_i ,

$$\sigma_i = \mathbf{e}_3 e^{-i\mathbf{e}_{\sigma\eta i} \beta_i}, \quad (41)$$

so that Eq. (40) reduces to

$$\sigma_0 = \mathbf{e}_3 e^{-i\beta'_i \mathbf{e}_{\sigma\eta i}}. \quad (42)$$

Expanding the exponential in Eq. (42), we get

$$\sigma_0 = \sin \beta'_i \mathbf{e}_1 e^{i\mathbf{e}_3 \phi_{\sigma_i}} + \cos \beta'_i \mathbf{e}_3. \quad (43)$$

On the other hand, using the expansion of σ_0 in Eq. (19c), we have

$$\sigma_0 = \cos \theta_{\sigma_0} \mathbf{e}_3 + \sin \theta_{\sigma_0} \mathbf{e}_1 e^{i\mathbf{e}_3 \phi_{\sigma_0}}. \quad (44)$$

Thus, equating Eqs. (43) and (44), we get

$$\theta_{\sigma_0} = \beta'_i, \quad (45a)$$

$$\phi_{\sigma_0} = \phi_{\sigma_i}, \quad (45b)$$

which is the same relations in [14], once we have changed the subscripts to match their notation.

B. Propagation from P_i to P_0

We define the entry point of the light ray when it intersects the base of the cylinder as \mathbf{r}_i :

$$\mathbf{r}_i = \rho_i \mathbf{e}_1 e^{i\mathbf{e}_3 \phi_i} = \rho_i \cos \phi_i \mathbf{e}_1 + \rho_i \sin \phi_i \mathbf{e}_2. \quad (46)$$

From position \mathbf{r}_i , the ray moves in the direction of σ_0 defined in Eq. (44), until it strikes the walls of the cylinder at position \mathbf{r}_0 , so that

$$\mathbf{r}_0 = s_0 \sigma_0 + \mathbf{r}_i, \quad (47)$$

where s_0 is the distance of propagation. If we define the radius of the cylinder to be R , then the position \mathbf{r}_0 can be written as

$$\mathbf{r}_0 = R \mathbf{e}_1 e^{i\mathbf{e}_3 \phi_{\eta_0}} + z_0 \mathbf{e}_3, \quad (48)$$

where ϕ_{η_0} is the azimuthal angle and z_0 is the distance along the axis, as illustrated in Fig. 4. Substituting Eq. (47) into Eq. (48), we get

$$s_0 \sigma_0 + \mathbf{r}_i = R \mathbf{e}_1 e^{i\mathbf{e}_3 \phi_{\eta_0}} + z_0 \mathbf{e}_3. \quad (49)$$

Notice that there are three unknowns in this equation: s_0 , ϕ_{η_0} , and z_0 .

Let us separate the axial and radial components of Eq. (49) to obtain

$$s_0 \cos \theta_{\sigma_0} \mathbf{e}_3 = z_0 \mathbf{e}_3, \quad (50a)$$

$$s_0 \sin \theta_{\sigma_0} \mathbf{e}_1 e^{i\mathbf{e}_3 \phi_{\sigma_0}} + \rho_i \mathbf{e}_1 e^{i\mathbf{e}_3 \phi_i} = R \mathbf{e}_1 e^{i\mathbf{e}_3 \phi_{\eta_0}}. \quad (50b)$$

Equation (50a) gives us our first equation relating s_0 and z_0 :

$$z_0 = s_0 \cos \theta_{\sigma_0}. \quad (51)$$

Now, squaring both sides of Eq. (50b) and using the exponential identities in Eq. (10), we get

$$s_0^2 \sin^2 \theta_{\sigma_0} + \rho_i^2 + 2s_0 \rho_i \sin \theta_{\sigma_0} \cos(\phi_i - \phi_{\sigma_0}) = R^2. \quad (52)$$

Solving for $s_0 \sin \theta_{\sigma_0}$ using the quadratic formula results to

$$s_0 \sin \theta_{\sigma_0} = \pm \sqrt{R^2 - \rho_i^2 \sin^2(\phi_i - \phi_{\sigma_0})} - \rho_i \cos(\phi_i - \phi_{\sigma_0}), \quad (53)$$

after simplifying the terms.

Notice that there are two possible solutions:

$$s_{0\pm} = \frac{1}{\sin \theta_{\sigma_0}} \left[\pm \sqrt{R^2 - \rho_i^2 \sin^2(\phi_i - \phi_{\sigma_0})} - \rho_i \cos(\phi_i - \phi_{\sigma_0}) \right]. \quad (54a)$$

The distance s_{0+} is the distance traveled by the light ray inside the fiber from the fiber's entrance to the cylindrical interface, while the distance s_{0-} is the distance traveled by the light ray if it propagates opposite to the direction σ_0 . The difference between these two distances is

Fig. 1. Relations of the cylindrical coordinate system as compared with Cartesian and spherical polar.

$$s_{0+} - s_{0-} = \frac{2}{\sin \theta_{\sigma_0}} \sqrt{R^2 - \rho_i^2 \sin^2(\phi_i - \phi_{\sigma_0})}, \quad (55)$$

which is a new result (see Fig. 5). If $\rho_i = 0$, then we get the meridional case:

$$s_{0+} - s_{0-} = \frac{2R}{\sin \theta_{\sigma_0}}. \quad (56)$$

On the other hand, if $\rho_i = R$,

$$s_{0+} - s_{0-} = \frac{2R |\cos(\phi_i - \phi_{\sigma_0})|}{\sin \theta_{\sigma_0}}, \quad (57)$$

which is similar to the form of the wall-to-wall propagation distance given by Cozannet and Treheux [28], except that for our case, s_{0-} is a virtual backward propagation from the fiber entrance.

Fig. 2. Vector $s_{k+1}\sigma_{k+1}$ is defined using two vectors with the same origin point, \mathbf{r}_k and \mathbf{r}_{k+1} .

Fig. 3. Propagation of the light ray inside the optical fiber in perspective view and top view. (a) The incident ray σ_i strikes the point P_i entrance end of the fiber where the normal vector is η_i . The angle of incidence is β_i and the angle of refraction is β'_i . From point P_i , the light ray enters the fiber and strikes the cylindrical walls at points P_0 , P_1 , and P_2 . (b) Top view of (a), with the points P'_0 , P'_1 , and P'_2 as the projections of the points P_0 , P_1 , and P_2 on the fiber's entrance.

Lastly, we solve for ϕ_{η_0} . Separating Eq. (50b) into the components of \mathbf{e}_1 and \mathbf{e}_2 , we get

$$s_0 \sin \theta_{\sigma_0} \cos \phi_{\sigma_0} + \rho_i \cos \phi_i = R \cos \phi_{\eta_0}, \quad (58a)$$

$$s_0 \sin \theta_{\sigma_0} \sin \phi_{\sigma_0} + \rho_i \sin \phi_i = R \sin \phi_{\eta_0}. \quad (58b)$$

Dividing Eq. (58a) by Eq. (58b), we obtain

$$\tan \phi_{\eta_0} = \frac{y_{\eta_0}}{x_{\eta_0}}, \quad (59)$$

where

$$x_{\eta_0} = s_0 \sin \theta_{\sigma_0} \cos \phi_{\sigma_0} + \rho_i \cos \phi_i, \quad (60a)$$

$$y_{\eta_0} = s_0 \sin \theta_{\sigma_0} \sin \phi_{\sigma_0} + \rho_i \sin \phi_i. \quad (60b)$$

Fig. 4. Vector \mathbf{r}_0 can be expressed as the sum of a rotating vector on the xy plane, $R\eta_0$, and a vertical component, $z_0\mathbf{e}_3$.

We note that $s_0 \sin \theta_{\sigma_0}$ is given in Eq. (53), so that the rectangular coordinates x_{η_0} and y_{η_0} of the normal vector η_0 are already defined in terms of the initial parameters. Thus, the cylindrical coordinates of the normal vector η_0 can now be determined, since the radius R of the fiber is constant and the azimuthal angle ϕ_{η_0} is given by Eq. (59).

C. Refraction at P_0 : Numerical Aperture

At point P_0 , on the fiber's cylindrical wall, the incident ray is σ_0 defined in Eq. (44), and the normal vector is

$$\eta_0 = \mathbf{e}_1 e^{ie_3 \phi_{\eta_0}}. \quad (61)$$

Their product is

$$\sigma_0 \eta_0 = \sin \theta_{\sigma_0} e^{ie_3(\phi_{\sigma_0} - \phi_{\eta_0})} - i \cos \theta_{\sigma_0} \mathbf{e}_2 e^{ie_3 \phi_{\eta_0}}, \quad (62)$$

where we used the exponential identities in Eq. (10). Separating the scalar and imaginary vector parts, we get

$$\sigma_0 \cdot \eta_0 = \sin \theta_{\sigma_0} \cos(\phi_{\sigma_0} - \phi_{\eta_0}), \quad (63)$$

$$\begin{aligned} \sigma_0 \times \eta_0 &= \mathbf{e}_1 \cos \theta_{\sigma_0} \sin \phi_{\eta_0} - \mathbf{e}_2 \cos \theta_{\sigma_0} \cos \phi_{\eta_0} \\ &\quad + \mathbf{e}_3 \sin \theta_{\sigma_0} \sin(\phi_{\sigma_0} - \phi_{\eta_0}), \end{aligned} \quad (64)$$

after removing the imaginary number i in the second equation. If we define ψ' as the angle between σ_0 and η_0 , then Eq. (63) yields

$$\cos \psi' = \sin \theta_{\sigma_0} \cos(\phi_{\sigma_0} - \phi_{\eta_0}), \quad (65)$$

which is essentially the same as that of Potter [11] and Senior [12].

Since ψ' is also the angle of incidence at point P_0 , then by Snell's law we have

$$n' \sin \psi' = n \sin \psi, \quad (66)$$

where ψ is the angle of refraction outside at point P_0 . For the ray to be trapped, we set $\psi = \pi/2$, so that

$$\sin \psi' = \frac{n}{n'}. \quad (67)$$

Combining Eqs. (65) and (67),

Fig. 5. If we extend $s_0 + \sigma_0$ backward, we obtain a vector of length s_{0+} , which will terminate at the fiber's wall, extended in the $-\mathbf{e}_3$ direction.

$$1 = \frac{n^2}{n'^2} + \sin^2 \theta_{\sigma_0} \cos^2(\phi_{\sigma_0} - \phi_{\eta_0}), \quad (68)$$

then solving for $\sin \theta_{\sigma_0}$, we get

$$\sin \theta_{\sigma_0} = \frac{\sqrt{n'^2 - n^2}}{n' |\cos(\phi_{\sigma_0} - \phi_{\eta_0})|}. \quad (69)$$

Now, the NA of an optical fiber is defined as

$$\text{NA} = n' \sin \theta_{\sigma_0}. \quad (70)$$

We combine Eqs. (69) and (70) to get

$$\text{NA} = \frac{\sqrt{n'^2 - n^2}}{|\cos(\phi_{\sigma_0} - \phi_{\eta_0})|}. \quad (71)$$

Equation (71) is the expression for the NA for skew rays in optical fibers as given by Potter [11,29] and Senior [12].

For the meridional approximation, we set $\phi_{\eta_0} = \phi_{\sigma_0}$, so that Eq. (71) reduces to the known standard form for the NA as given by Klein and Furtak [15] and Potter [11]:

$$\text{NA} = \sqrt{n'^2 - n^2}. \quad (72)$$

If we expand the denominator in Eq. (71), we get

$$\cos(\phi_{\sigma_0} - \phi_{\eta_0}) = \cos \phi_{\sigma_0} \cos \phi_{\eta_0} + \sin \phi_{\sigma_0} \sin \phi_{\eta_0}. \quad (73)$$

Since

$$\cos \phi_{\eta_0} = x_{\eta_0}/R, \quad (74a)$$

$$\sin \phi_{\eta_0} = y_{\eta_0}/R, \quad (74b)$$

then using Eq. (60) together with trigonometric identities, we obtain

$$\cos(\phi_{\sigma_0} - \phi_{\eta_0}) = \frac{s_0}{R} \sin \theta_{\sigma_0} + \frac{\rho_i}{R} \cos(\phi_i - \phi_{\sigma_0}). \quad (75)$$

Substituting Eq. (75) back into Eq. (71) results to

$$\text{NA} = \frac{\sqrt{n'^2 - n^2}}{\left| \frac{s_0}{R} \sin \theta_{\sigma_0} + \frac{\rho_i}{R} \cos(\phi_i - \phi_{\sigma_0}) \right|}. \quad (76)$$

Combining this with the expression for s_0 in Eq. (54a) and using the identity $\phi_{\sigma_0} = \phi_{\sigma_i}$ from Eq. (45b), we arrive at

$$\text{NA} = \chi \sqrt{n'^2 - n^2}, \quad (77)$$

where

$$\chi = \frac{1}{\sqrt{1 - \frac{\rho_i^2}{R^2} \sin^2(\phi_i - \phi_{\sigma_i})}}. \quad (78)$$

Equation (77) forms the expression for the NA for the skew rays in optical fibers. Here we introduce the skew factor χ , which is defined in terms of the initial ray parameters at the fiber entrance: the position $\mathbf{r}_i = (\rho_i, \phi_i, 0)$ in cylindrical coordinates where the incident ray $\sigma_i = (1, \phi_{\sigma_i}, \theta_{\sigma_i})$ in spherical coordinates. Notice that the skew factor depends on the azimuthal angle ϕ_{σ_i} of the incident ray, but not on the polar angle θ_{σ_i} .

The expression for the NA in terms of the skew factor χ is a new result. To arrive at the meridional case in Eq. (72), we set the radial distance $\rho_i = 0$, to get the skew factor $\chi = 1$. On the other hand, if we set the initial position at the edge of the fiber, i.e., $\rho_i = R$, we get

$$\chi = \frac{1}{\sqrt{\cos^2(\phi_{\sigma_0} - \phi_{\eta_0})}}, \quad (79)$$

which leads to Eq. (71), the NA for skew rays given in the literature. Figure 6 shows the plot of the skew factor χ as a function of the normalized radial distance ρ_i/R and the difference of the azimuthal angles $\phi_i - \phi_{\sigma_i}$.

D. Reflection at P_0

At position \mathbf{r}_0 on the interface, the light ray's propagation vector is σ_0 and the normal vector to the interface is η_0 :

$$\sigma_0 = \cos \theta_{\sigma_0} \mathbf{e}_3 + \sin \theta_{\sigma_0} \mathbf{e}_1 e^{ie_3 \phi_{\sigma_0}}, \quad (80a)$$

$$\eta_0 = \mathbf{e}_1 e^{ie_3 \phi_{\eta_0}}. \quad (80b)$$

To obtain the new propagation vector σ_1 after reflection, we use the law of reflection in Eq. (22):

$$\sigma_1 = -\eta_0 \sigma_0 \eta_0. \quad (81)$$

Substituting the expressions for η_0 in Eq. (80b), and σ_0 in Eq. (80a) into Eq. (81), yields

$$\sigma_1 = -\sin \theta_{\sigma_0} \mathbf{e}_1 e^{ie_3(2\phi_{\eta_0} - \phi_{\sigma_0})} + \cos \theta_{\sigma_0} \mathbf{e}_3, \quad (82)$$

Fig. 6. Skew factor χ as a function of the ratios of the relative radii ρ/R and the azimuthal angular difference $\phi_i - \phi_{\sigma_i}$.

after distributing the terms and simplifying the result. Equation (82) is the desired equation for the new propagation vector σ_1 .

Using the definition of σ_1 as written in Eq. (19c),

$$\sigma_1 = \sin \theta_{\sigma_1} \mathbf{e}_1 e^{ie_3 \phi_{\sigma_1}} + \cos \theta_{\sigma_1} \mathbf{e}_3, \quad (83)$$

and comparing this with the expression for σ_1 in Eq. (83), we obtain [14]

$$\theta_{\sigma_1} = -\theta_{\sigma_0}, \quad (84a)$$

$$\phi_{\sigma_1} = 2\phi_{\eta_0} - \phi_{\sigma_0}. \quad (84b)$$

Notice that Eq. (84a) is not proper as we previously defined θ to have values between 0 to π .

In order to avoid having to write the negative sign before the θ , we can use the following relation derived from the Euler identity:

$$e^{ie_3(\pm\pi)} = \cos(\pm\pi) + ie_3 \sin(\pm\pi) = -1, \quad (85)$$

so that Eq. (82) becomes

$$\sigma_1 = \sin \theta_{\sigma_0} \mathbf{e}_1 e^{ie_3(2\phi_{\eta_0} - \phi_{\sigma_0} \pm \pi)} + \cos \theta_{\sigma_0} \mathbf{e}_3. \quad (86)$$

Hence,

$$\theta_{\sigma_1} = \theta_{\sigma_0}, \quad (87a)$$

$$\phi_{\sigma_1} = 2\phi_{\eta_0} - \phi_{\sigma_0} \pm \pi, \quad (87b)$$

which is similar to what we have derived in a previous paper [14]. Notice that Eq. (87a) is now in the proper form of θ , except that the sign of π in Eq. (87b) must be determined for individual cases.

E. Propagation from P_0 to P_1

From the propagation law in Eq. (18), we know that the final position of the ray depends on its initial position \mathbf{r}_0 :

$$\mathbf{r}_1 = s_1 \sigma_1 + \mathbf{r}_0, \quad (88)$$

where s_1 and σ_1 are the ray's propagating distance and direction, respectively. This is shown in Fig. 7. If we use the expression of \mathbf{r}_0 in Eq. (48) and express \mathbf{r}_1 in a similar form, then Eq. (88) becomes

$$s_1 \sigma_1 + R \mathbf{e}_1 e^{ie_3 \phi_{\eta_0}} + z_0 \mathbf{e}_3 = R \mathbf{e}_1 e^{ie_3 \phi_{\eta_1}} + z_1 \mathbf{e}_3. \quad (89)$$

Separating Eq. (89) into its radial and axial components, we get

$$s_1 \sin \theta_{\sigma_1} \mathbf{e}_1 e^{ie_3 \phi_{\sigma_1}} + R \mathbf{e}_1 e^{ie_3 \phi_{\eta_0}} = R \mathbf{e}_1 e^{ie_3 \phi_{\eta_1}}, \quad (90a)$$

$$s_1 \cos \theta_{\sigma_1} \mathbf{e}_3 + z_0 \mathbf{e}_3 = z_1 \mathbf{e}_3. \quad (90b)$$

Notice that there are three unknowns in Eq. (90): s_1 , ϕ_{η_1} , z_1 .

To solve for the propagation distance s_1 , we first square both sides of Eq. (90a):

$$s_1^2 \sin^2 \theta_{\sigma_1} + R^2 + 2s_1 R \sin \theta_{\sigma_1} \cos(\phi_{\eta_0} - \phi_{\sigma_1}) = R^2. \quad (91)$$

Hence,

$$s_1 = -\frac{2R \cos(\phi_{\eta_0} - \phi_{\sigma_1})}{\sin \theta_{\sigma_1}}. \quad (92)$$

To solve for ϕ_{η_1} , we expand Eq. (90a) into its \mathbf{e}_1 and \mathbf{e}_2 components:

$$R \cos \phi_{\eta_1} = s_1 \sin \theta_{\sigma_1} \cos \phi_{\sigma_1} + R \cos \phi_{\eta_0}, \quad (93a)$$

$$R \sin \phi_{\eta_1} = s_1 \sin \theta_{\sigma_1} \sin \phi_{\sigma_1} + R \sin \phi_{\eta_0}. \quad (93b)$$

Dividing the two equations and using the expression for s_1 in Eq. (92), we get

$$\tan \phi_{\eta_1} = \frac{\sin \phi_{\eta_0} \cos 2\phi_{\sigma_1} - \cos \phi_{\eta_0} \sin 2\phi_{\sigma_1}}{-\cos \phi_{\eta_0} \cos 2\phi_{\sigma_1} - \sin \phi_{\eta_0} \sin 2\phi_{\sigma_1}}, \quad (94)$$

after using the double angle identities. Hence,

$$\tan \phi_{\eta_1} = \frac{-\sin(2\phi_{\sigma_1} - \phi_{\eta_0})}{-\cos(2\phi_{\sigma_1} - \phi_{\eta_0})}. \quad (95)$$

Note that we retained the negative signs in both the numerator and denominator so that we can properly determine the angle ϕ_{η_1} , which is from 0 to 2π .

4. SKEW RAY INVARIANTS

A. Propagation Distance Between Reflections

The procedure for computing the propagation of the light ray from P_1 to P_2 is the same as the procedure from P_0 to P_1 . Therefore, we can simply change the subscripts to obtain the following relations for the propagation distance s_2 , the propagation polar angle θ_{σ_2} , and the propagation azimuthal angle ϕ_{σ_2} :

$$s_2 = -\frac{2R \cos(\phi_{\eta_1} - \phi_{\sigma_2})}{\sin \theta_{\sigma_2}}, \quad (96a)$$

$$\theta_{\sigma_2} = \theta_{\sigma_1}, \quad (96b)$$

$$\phi_{\sigma_2} = 2\phi_{\eta_1} - \phi_{\sigma_1} \pm \pi. \quad (96c)$$

Notice that the angle θ_{σ} remains constant through reflections. Our aim is to show that the propagation distance s is also constant between reflections, i.e., $s_1 = s_2$.

If we substitute Eqs. (96b) and (96c) into Eq. (96a), we get

$$s_2 = \frac{2R \cos(-\phi_{\eta_1} + \phi_{\sigma_1})}{\sin \theta_{\sigma_1}}, \quad (97)$$

since $\cos(\phi - \pi) = -\cos \phi$. Expanding Eq. (97) using a trigonometric identity, and using the expression for the sines and cosines of ϕ_{η_1} in Eq. (95),

$$\sin \phi_{\eta_1} = -\sin(2\phi_{\sigma_1} - \phi_{\eta_0}), \quad (98)$$

$$\cos \phi_{\eta_1} = -\cos(2\phi_{\sigma_1} - \phi_{\eta_0}), \quad (99)$$

we obtain

$$s_2 = -\frac{2R \cos(\phi_{\eta_0} - \phi_{\sigma_1})}{\sin(\theta_{\sigma_1})}. \quad (100)$$

Comparing this with the expression for s_1 in Eq. (92), we arrive at

$$s_1 = s_2. \quad (101)$$

Thus, the propagation distance between two reflections is constant.

B. Axial Distance Between Reflections

The axial position z_1 of point P_1 is given in Eq. (90b):

$$z_1 = s_1 \cos \theta_{\sigma_1} + z_0. \quad (102)$$

Similarly, we can show that for point P_2 ,

$$z_2 = s_2 \cos \theta_{\sigma_2} + z_1. \quad (103)$$

Taking the difference of Eq. (102) and Eq. (103), and imposing $s_2 = s_1$ in Eq. (100) and $\theta_{\sigma_2} = \theta_{\sigma_1}$ in Eq. (96b), then

$$\Delta z = z_2 - z_1 = z_1 - z_0. \quad (104)$$

Thus, the axial distance Δz between wall-to-wall propagations, defined as the pitch, is constant.

If we substitute the expression for z_1 in Eq. (102) and s_1 in Eq. (92), we get

$$\Delta z = -2R \cos(\phi_{\eta_0} - \phi_{\sigma_1}) \cot \theta_{\sigma_1}, \quad (105)$$

which is similar in form to that given in Eq. (22) of Cozannet and Treheux [28]. Alternatively, we can express Δz in terms of s_1 in Eq. (92) to get

$$\Delta z = s_1 \cos \theta_{\sigma_1}, \quad (106)$$

which is an invariant given in Love and Snyder [3]. Note that this invariant reduces only to the ray half-period if the rays are meridional.

C. Change in Azimuthal Angle Between Reflections

We know from Eq. (95) that the azimuthal angle ϕ_{η_1} at point P_1 is given by

$$\phi_{\eta_1} = \tan^{-1} \left(\frac{-\sin(2\phi_{\sigma_1} - \phi_{\eta_0})}{-\cos(2\phi_{\sigma_1} - \phi_{\eta_0})} \right), \quad (107)$$

so that

$$\phi_{\eta_1} = 2\phi_{\sigma_1} - \phi_{\eta_0} + k\pi, \quad (108)$$

where k is +1, -1, or 0.

To find k , we substitute the expression for ϕ_{η_1} in Eq. (108), for ϕ_{σ_2} in Eq. (96c), and $\sin(\theta_{\sigma_1})$ in Eq. (96b) to Eq. (96a) to obtain

$$s_2 = -\frac{2R \cos(2\phi_{\sigma_1} - \phi_{\eta_0} - 2\phi_{\eta_1} + \phi_{\sigma_1} + (k\mp 1)\pi)}{\sin \theta_{\sigma_1}}. \quad (109)$$

Substituting the expression for ϕ_{η_1} in Eq. (108) again and rearranging the terms, we get

$$s_2 = -\frac{2R \cos(-\phi_{\sigma_1} + \phi_{\eta_0} + (-k\mp 1)\pi)}{\sin \theta_{\sigma_1}}. \quad (110)$$

Comparing this the expression for s_2 in Eq. (100), we arrive at $k = \mp 1$, so that Eq. (108) reduces to

$$\phi_{\eta_1} = 2\phi_{\sigma_1} - \phi_{\eta_0} \mp \pi. \quad (111)$$

Using a similar process, we can show that the form of ϕ_{η_2} and ϕ_{η_3} are similar to ϕ_{η_1} ,

$$\phi_{\eta_2} = 2\phi_{\sigma_2} - \phi_{\eta_1} \mp \pi, \quad (112a)$$

$$\phi_{\eta_3} = 2\phi_{\sigma_3} - \phi_{\eta_2} \mp \pi, \quad (112b)$$

so that

$$\phi_{\eta_2} - \phi_{\eta_1} = 2(\phi_{\sigma_2} - \phi_{\eta_1}) \mp \pi, \quad (113a)$$

Fig. 7. Light ray traveled from point \mathbf{r}_0 to point \mathbf{r}_1 on the fiber's walls, at a distance s_1 , along the direction σ_1 . The normal vectors at the two points are η_0 and η_1 .

$$\phi_{\eta_3} - \phi_{\eta_2} = 2(\phi_{\sigma_3} - \phi_{\eta_2}) \mp \pi. \quad (113b)$$

Replacing the subscripts of Eq. (96c) to obtain an expression for ϕ_{σ_3} ,

$$\phi_{\sigma_3} = 2\phi_{\eta_3} - \phi_{\sigma_2} \pm \pi, \quad (114)$$

and using the expressions for ϕ_{σ_3} in Eq. (114) and ϕ_{η_2} in Eq. (112a), Eq. (113b) becomes

$$\phi_{\eta_3} - \phi_{\eta_2} = 2(\phi_{\sigma_2} - \phi_{\eta_1}) \mp \pi. \quad (115)$$

Comparing Eq. (113a) with Eq. (115), we arrive at

$$\Delta\phi = \phi_{\eta_3} - \phi_{\eta_2} = \phi_{\eta_2} - \phi_{\eta_1}. \quad (116)$$

Thus, the change in the azimuthal angle $\Delta\phi$ between consecutive reflections is a constant.

So now we have two invariants between consecutive reflections: the change in azimuthal angle $\Delta\phi$ and the change in the axial propagation distance Δz . From this, we conclude that the rays inside a fiber trace a polygonal helix.

5. CONCLUSIONS

In this paper, we used geometric algebra to compute the paths of skew rays in a cylindrical, step-index optical fiber. To do this, we used the vector addition form for the law of propagation, the exponential of an imaginary vector form for the law of refraction, and the vector product form for the law of reflection. In addition, we used the spherical angles θ and ϕ to describe the directions of rays in space, but expressed in cylindrical coordinates in exponential form. We showed that the light rays inside the optical fiber trace a polygonal helical path characterized by three invariants between successive reflections: (1) the ray path distance, (2) the change in axial distances, and (3) the change in the azimuthal angles. We also showed that the NA for skew rays we obtained is the same as that in the literature.

To derive the ray tracing invariants, we did not use the reflection and refraction laws in Klein and Furtak [15]. Rather, we used two alternative techniques: (a) the Pauli identity, which expresses the geometric product of two vectors as a sum of their dot and imaginary cross products, and (b) the Euler's theorem, which expresses the exponential of an imaginary vector as a sum of the cosine of the magnitude of the vector and the product of the normalized imaginary vector with the sine of the vector's magnitude. These two theorems allow us to express vector rotations in exponential form, which enables us to take advantage of the addition or subtraction of exponential arguments of two rotated vectors in the derivation of the ray tracing invariants.

Many of the equations for the invariants were already known before, except maybe for the change in the azimuthal angle between reflections. Also, we obtained a new expression for the NA, which allows the point of entry of light to be an arbitrary point in the fiber's entrance, and not limited to the center or the edge as given by previous authors. Finally, our use of standard notations for the angles θ and ϕ for cylindrical and spherical coordinates, differentiated only by subscripts, would hopefully help in visualizing the complex geometry of skew ray tracing.

In future papers, we shall extend our work on skew rays to ray tracing in circular, conical, and toroidal fibers, which may be step-index, multistep-index, or graded-index.

Thanks to James Hernandez for checking the readability of the manuscript. This work was supported by Manila Observatory and Ateneo de Manila University.
